COVID-19 vaccine clinical trials for Cavite residents to start in two weeks - Jonvic

The clinical trials for vaccines against COVID-19 involving Cavite residents would begin in the next two weeks, Gov. Jonvic Remulla said last Aug. 28.

In a television interview, Remulla said the local government has identified the high-risk individuals who would join the trials, including policemen, drivers of public transport vehicles, factory workers, and service citizens.

"It's not Cavite per se but Cavite and La Salle DSC the medical school. They have a very good track record in epidemiology and

27 Pangasinense students stranded in Silang return home

Some 27 senior high school graduates stranded in Silang, Cavite have returned with their families after the provincial govern-

ment of Pangasinan facilitated their return to the province. In a statement last Aug. 26, the Provincial Information Office (PIO) and the students' school

stated that they were composed of 14 males and 13 females who graduated from Pangasinan since the start of the lockdown in March. Several of

Transplanted brown-fat-like cells hold promise for obesity and diabetes

Obesity is the main cause of type 2 diabetes and related chronic illnesses that together will kill more people around the globe this year than the Covid-19 coronavirus, scientists at Joslin Diabetes Center have delivered a proof of concept for a novel cell-based therapy against this dangerous condition.

The potential therapy for obesity would transplant HUMBLE (human brown-like) fat cells, human white fat cells that have been genetically modified to become similar to heat-generating brown fat cells, says Yu-Hua

fat cells, says Yu-Hua Teng, PhD, a Senior Investigator in Joslin's Section on Integrative Physiology and Metabolism.

Brown fat cells burn energy instead of storing energy as white fat cells do, says Teng, senior author on a paper about the work in Science Translational Medicine. In the process, brown fat can lower excessive levels of glucose and lipids in the blood that are linked to metabolic diseases such as diabetes.

loss of this beneficial brown fat — a barrier that HUMBLE cells are designed to overcome, Teng says.

She and her colleagues created the cells from human white fat cells in a progenitor stage (not yet fully developed into their final fat form). The investigators used a variant of the CRISPR-Cas9 genome editing system to boost expression of a gene called UCP1, which triggers white fat cell progenitors to develop into brown-fat-like cells.

Transplanted into mice lacking an immune response, the HUMBLE brown fat — a barrier that HUMBLE cells are designed to overcome, Teng says.

day in the area being tasked to join in this medical trial. Cavite will help La Salle HSI in getting the high-risk people in getting the vaccine trial. It should start in the next two weeks," Remulla told ANC.

Earlier, Remulla said at least 10,000 Cavite residents are set to be subjected to a Phase 1 field trial of two-phases clinical programs for a COVID-19 vaccine.

He said the students would undergo week testing first before being subjected to clinical trials.

He also said about 100 students who would be part of the trial is not located in one barracks but the entire Cavite province. Remulla also said it would take a month to know the result of the medical trials.

(27... from page 1)

The students were latched on August 23 by the provincial government's shuttle buses from Cavite to their respective homes, it added.

"Inclusive of the free transportation, the locally attended individuals were treated with meals and family packs," the PSC said.

It said the students were not allowed to be visited by their family members but the restriction did not totally block their communication.

"The parents or guardians of the students were allowed to contact with their sons and daughters via scheduled phone calls using the institution's communication lines (the students who do not have cellular phones). With stricter administrative policies, the students were not allowed to go out of the school premises at all to safeguard their health and ensure their safety," the PSC said.

Polymers prevent potentially hazardous mist during dentist visit

Researchers at the **University of Illinois** are using vibrating beds in a Chicago clinic? **dentist's office** that have

water into mist and send it flying into the air if that mist contains a virus or some other pathogen. It is a health hazard for dentists and patients.

In a paper published last week in *Physics of Fluids*, by AIP Publishing, **Alexander Yarin** and his colleagues discovered that the focus of a vibrating tool or dentist's drill are so much for the vacuumic properties of food-grade polymers, such as polyacrylic acid, which they used as a small substitute to water in dental settings.

Their results were surprising, but only did a small substitute of polymers completely eliminate atomization, but it did so with ease, exhibiting fundamental polymer physics, such as coil-stretch transition, that served the intended purpose beautifully.

They would use DNA-approved polymers, polyacrylic acid proved more effective than another gum, because in addition to its high elongational viscosity (high elastic stress in stretching), it revealed a relatively low shear elasticity, which makes pumping it easy.

Tethering together type 2 diabetes drugs increases efficacy of combination therapy

Biomedical engineering researchers at Duke University have shown that the efficacy of a two-pronged type 2 diabetes treatment increases when the drugs are linked by a fast-acting tether rather than simply co-administered. The combination molecule is formed by an insulin-like polypeptide (ILP) linker that forms a gel-like depot when injected under the skin, which slowly dissolves and releases the active drug over time.

Because GLP-1, a short peptide, and PEG21, a large folded protein, are each different compounds, these findings suggest that this approach to combination drug design could be applied to disease therapies beyond diabetes.

The results appear online on August 28 in the journal *Nature Advances Science*.

"In the burgeoning field of multi-functioning single-molecule diabetes drug designs, researchers primarily create drugs that are either the same structure and function," said Cathie

Gilroy, a postdoctoral scholar at the University of California, Berkeley, who led the project while completing her PhD in biomedical engineering at Duke. "Being able to combine such structurally distinct drugs into a single molecule while maintaining the bioactivity and stability of each is a big technological achievement."

Type 2 diabetes is a progressive disease where body tissues become resistant to the effects of insulin, which regulates the movement of sugar from the blood stream into cells. When this carefully tuned system breaks down, blood sugar levels remain unusually elevated and a host of serious complications can follow. While many treatment options exist,

a single drug is rarely able to treat an advanced case. Conventional medications lose their potency over time and frequently cause weight gain, which itself can promote insulin resistance and exacerbate the disease.

A growing class of drugs is based on GLP-1, a naturally occurring peptide released from the intestine after a meal. GLP-1 therapy enhances the release of insulin from the pancreas while promoting weight loss.

However, the high doses of GLP-1 that are sometimes necessary to maintain healthy blood sugar levels have been shown to cause gastrointestinal distress. Researchers are exploring combination therapies that strategically pair

GLP-1 with additional drugs to maximize glucose control, minimize side effects and augment weight loss.

While most drug combinations incorporate small peptides from the same family as GLP-1, Gilroy and Ashraf Chikhi, the Alexander Chikhi Distinguished Professor of Biomedical Engineering at Duke, chose to work with PEG21, a natural killer toxin. PEG21 regulates insulin sensitivity, energy expenditure and fat metabolism within body tissues.

"PEG21 functions through a different mechanism than GLP-1, and we hypothesized that the two drugs would complement each other nicely" and Gilroy said.

"GLP-1 increases insulin secretion by the pancreas, while PEG21 enhances the body's response to the insulin. GLP-1 reduces food intake, while PEG21 helps burn more calories."

But rather than simply injecting diabetes drugs with both drugs at the same time, the researchers decided to link GLP-1 and PEG21 together into a single molecule. This approach to combination therapy has several advantages. A single molecule is more predictable in how it will disperse through the body, and even more likely to be absorbed.

A single drug is also beneficial for the prescribing physician and patient, as it reduces the medication burden and simplifies the treatment regimen.

Got fatigue? Study further pinpoints brain regions that may control it

Scientists at Johns Hopkins Medicine using MRI scans and computer modeling in the brain and how they have further pinpointed areas of the human brain that regulate efforts to deal with fatigue.

The findings, they say, could advance the development of behavioral and other strategies that increase physical performance in healthy people, and also illuminate the neural mechanisms that contribute to fatigue in people with depression, multiple sclerosis and stroke.

Results of the research were published online Aug. 12 in *Nature Communications*.

"We know the physiologic processes involved in fatigue, such as lactic acid build-up in muscles,

but we know far less about how feelings of fatigue are processed in the brain and how our brain decides how much and what kind of effort to make to overcome fatigue," says Vikram Chib, Ph.D., assistant professor of biomedical engineering at the Johns Hopkins University School of Medicine and research scientist at the Kennedy Krieger Institute.

Knowing the brain regions that control choices about fatigue moderating efforts can help scientists find therapies that precisely alter those choices, says Chib. "It might not be ideal for your brain to simply power through fatigue," says Chib. "It might be more beneficial for the brain to be more efficient about the signals it's

sending."

For the study, Chib first developed a novel way to objectively quantify how people "feel" fatigue, a difficult task because rating systems can vary from person to person. Physicians often ask their patients to rate their fatigue on a scale of 1 to 7, but like pain scales, such ratings are subjective and varied.

To standardize the metric for fatigue, Chib asked 20 study participants to make risk-based decisions about exerting a specific physical effort. The average age of participants was 24 and ranged from 18 to 34. Nine of the 20 were female.

The 20 participants were asked to grip and squeeze a sensor after training them to recognize a scale of ef-

fort. For example, zero was equal to no effort and 50 units of effort were equal to half the participant's maximum force. The participants learned to associate units of effort with how much to squeeze, which helped to standardize the effort level among individuals.

The participants repeated the grip exercises for 17 blocks for 10 trials each, until they were fatigued, then were offered one of two choices for making each effort. One was a random ("risky") choice based on a coin flip, offering the chance to exert no effort or a predetermined effort level. The other choice was a predetermined effort level, by introducing uncertainty, the researchers were tapping in to how each

subject valued their effort—a way, in effect, of shedding light on how their brains and minds decided how much effort to make.

Based on whether the participant chose a risky option versus the predetermined one, the researchers used computerized programs to measure how participants felt about the prospect of exerting particular amounts of effort while they were fatigued.

"Unsurprisingly, we found that people tend to be more risk-averse—to avoid—effort," says Chib. Most of the participants (19 of 20) opted for the random choice of a predetermined effort level. This means that, when fatigued, participants were less willing to take the chance of having to

exert large amounts of effort.

"The predetermined amount had to get pretty high in relative effort for participants to choose the coin toss option," says Chib.

Among a separate group of 10 people trained on the gripping system but not given numerous, fatiguing trials, there was no significant tendency toward picking either the risky coin toss or defined effort.

Chib's research team also evaluated participants' brain activity during the gripping exercises using functional magnetic resonance imaging (fMRI) scans, which track blood flow through the brain and show which neurons are firing most often.

Genomic analysis reveals many animal species may be vulnerable to SARS-CoV-2 infection

Humans are not virus to land and gain the only species facing entry into cells. a potential threat from SARS-CoV-2, the novel coronavirus that causes COVID-19, according to a new study from the University of California, Davis.

An international team of scientists used genomic analysis to compare the main cellular receptor for the virus in humans – angiotensin-converting enzyme 2, or ACE2 – in 410 different species of vertebrates, including birds, fish, amphibians, reptiles and mammals.

ACE2 is normally found on many different types of cells and tissues, including epithelial cells in the nose, mouth and lungs. In humans, 25 amino acids of the ACE2 protein are important for the

entry into cells. The researchers used these 25 amino acid sequences of the ACE2 protein, and modeling of its predicted protein structure together with the SARS-CoV-2 spike protein, to evaluate how many of these amino acids are found in the ACE2 protein of the different species. “Animals with all 25 amino acid residues matching the human protein are predicted to be at the highest risk for contracting SARS-CoV-2 via ACE2,” said James Thomas, first author for the paper and a postdoctoral research associate at UC Davis.

“The risk is predicted to decrease the more the species ACE2 has matching residues dif-

fer from humans.” About 40 percent of the species potentially susceptible to SARS-CoV-2 are classified as “threatened” by the International Union for Conservation of Nature and may be especially vulnerable to human-to-animal transmission. The study was published Aug. 21 in the Proceedings of the National Academy of Sciences.

“The data provide an important starting point for identifying vulnerable and threatened animal populations at risk of SARS-CoV-2 infection,” said Harry Lewin, lead author for the study and a distinguished professor of evolution and ecology at UC Davis. “We hope it inspires practices that protect both animal and hu-

man health during the pandemic.” Several critically endangered primate species, such as the Western lowland gorilla, Sumatran orangutan and Northern white-cheeked gibbon, are predicted to be at very high risk of infection by SARS-CoV-2 via their ACE2 receptor.

Other animals flagged as high risk include marine mammals such as grey whales and bottlenose dolphins, as well as Chinese hamsters.

Domestic animals such as cats, cattle and sheep were found to have a medium risk, and dogs, horses and pigs were found to have low risk for ACE2 binding. How this relates to infection and disease

risk needs to be determined by future studies, but for those species that have known infectivity data, the correlation is high.

In documented cases of SARS-CoV-2 infection in mink, cats, dogs, hamsters, lions and tigers, the virus may be using ACE2 receptors or they may use receptors other than ACE2 to gain access to host cells. Lower propensity for binding could translate to lower propensity for infection, or lower ability for the infection to spread to an animal or between animals once established.

Because of the potential for animals to contract the novel coronavirus from humans and vice versa, institutions including the National Zoo and the San

Diego Zoo, which both contributed genomic material to the study, have strengthened programs to protect both animals and humans.

“Zoonotic diseases and how to prevent human to animal transmission is not a new challenge to us and animal care professionals,” said co-author Klaus-Peter Koepfli, senior research scientist at Smithsonian-Mason School of Conservation and former conservation biologist with the Smithsonian Conservation Biology Program’s Human’s Center for Species Survival and Center for Conservation Genetics. This new information allows us to focus our efforts and plan accordingly to keep animals

Placenta can indicate how body responds to opioids during pregnancy

Scientists at the faculty member in the birth weight. But, so far no one has studied the use of this drug during pregnancy can negatively affect the placenta's structure, such as reducing and killing cells that produce by-products needed for normal brain development. In addition, Rosenfeld said their findings show specific differences in genetic expressions between female and male placentas in response to maternal

Scientists at the University of Missouri Thompson Center for Autism and Neurodevelopmental Disorders, they hope could one day help identify the presence of an opioid use disorder during human pregnancy. Cheryl S. Eissenfeld, an author on the study, said women often take opioids for pain regulation during pregnancy, including oxycodone, so it's important to understand the effects of these drugs on the fetal placenta, a temporary organ that is essential in providing nutrients from a mother to her unborn child. Rosenfeld is a professor of biomedical sciences in the College of Veterinary Medicine, assistant professor in the Christopher S. Bond Life Sciences Center and research

blood. They found that use of this drug during pregnancy can negatively affect the placenta's structure, such as reducing and killing cells that produce by-products needed for normal brain development. In addition, Rosenfeld said their findings show specific differences in genetic expressions between female and male placentas in response to maternal oxycodone exposure. "Our results show when mothers take oxycodone during pregnancy, it causes severe placental disruptions, including elevation of certain gene expressions," Rosenfeld said. "We know what the normal levels should be and if there are any changes, then we know something might have triggered such effects. For

instance, in response to material oxycodone exposure, female placentas start increasing production of key genes essential in regulating maternal physiology. However, in male placentas, we see some of these same genes are reduced in expression. These expression patterns could be potential biomarkers for detecting exposure to oxycodone use." Rosenfeld said by studying this in an animal model, it allows scientists to see these changes quicker than if they were completing a comparable study in people, because a pregnant mouse can give birth in 21 days compared to about nine months in people. "This also allows us to study other regions of the body,

especially the brain of exposed offspring, that would be affected by taking these opioids," Rosenfeld said. "We can then use this information to help epidemiologists identify behaviors that people should be looking at in children whose mothers have taken these opioids."

Rosenfeld suggests that opioids should be added to other widely discussed warning factors during pregnancy, such as smoking and drinking alcohol. She said short-term use of opioids by pregnant women, such as someone who has kidney stones, might not cause much of an effect on their pregnancy, but that likely depends on when the mother is taking the drug while pregnant.

Researchers unravel two mysteries of COVID-19

A team from Lawson Health Research Institute and Western University has made significant steps toward understanding COVID-19 through two back-to-back studies published last week in Critical Care Explorations. In one study, the team has identified molecules that can be used as biomarkers to predict how severely a patient will become ill. In the other study, they are the first to reveal a new mechanism causing blood clots in COVID-19 patients and potential ways to treat them.

The studies were conducted by analysing blood samples from critically ill patients at London Health Sciences Centre (LHSC) at LHSC. "While the findings need to be validated with larger groups of patients, they could have important implications for treating and studying this disease."

With one COVID-19 patient admitted to intensive care unit (ICU) do not survive.

"When a patient is admitted to ICU, we normally wait to see if they are going to get worse before we consider any early interventions."

"There is a great need for a simple and rapid troponin test for patients with chest pain in the pre-hospital setting," said study author Dr. Roi Westreich of Soroka University Medical Centre, Beer Sheva, Israel. "Current troponin testing uses blood samples. In this preliminary study we evaluated the feasibility of a novel method using saliva."

The purpose of the study was to see if cardiac troponin could be detected in the saliva of patients with heart muscle injury.

The innovative technique requires patients to spit into a tube and provides results in 10 minutes, compared to at least one hour for the standard blood test.

Heart attacks need urgent diagnosis, followed by treatment to restore blood flow to blocked arteries. Diagnosis is based on symptoms (such as chest pain), an electrocardiogram (ECG) and a blood test for cardiac troponin, a protein released into the blood when the heart muscle is injured.
